# Explicit and Implicit Inductive Bias in Deep Learning Nati Srebro (TTIC) 

 Ryota Tomioka (TTIC $\rightarrow$ MSR), Srinadh Bhojanapalli (TTIC $\rightarrow$ Google), Blake Woodworth, Pedro Savarese, David McAllester (TTIC), Greg Ongie, Becca Willett (Chicago), Daniel Soudry, Elad Hoffer, Mor Shpigel, Edward Moroshko, Itay Golan (Technion), Shahar Azulai, Amir Globerson (Tel-Aviv), Ziwei Ji, Matus Telgarsky (UIUC), Ashia Wilson, Becca Roelofs, Mitchel Stern, Ben Recht (Berkeley), Russ Salakhutdinov (CMU), Jason Lee, Zhiyuan Li (Princeton), Yann LaCun (NYU/Facebook)
## Plan

-What io mean by "Inductive Bias"?

- Inductive Bias in Deep Learning: The Role of Implicit Optimization Bias
- The "complexity measure" approach for understanding Deep Learning

## (break)

- Examples of Identifying the Implicit Bias and "complexity measure"
- Squared Loss vs Logistic Loss
- Effect of initialization and other parameters
- Explicit Regularization vs Implicit Bias
- Can implicit bias be described in terms of a complexity measure?
- Supervised Learning: find $h: \mathcal{X} \rightarrow \mathcal{Y}$ with small generalization error

$$
L(h)=\mathbb{E}_{(x, y) \sim \mathcal{D}}[\operatorname{loss}(h(x) ; y)]
$$

based on samples $S$ (hopefully $S \sim \mathcal{D}^{m}$ ) using learning rule:

$$
\left.A: S \mapsto h \quad \text { (i.e. } A:(\mathcal{X} \times \mathcal{Y})^{*} \rightarrow \mathcal{Y}^{X}\right)
$$

- No Free Lunch: For any learning rule, there exists a source $\mathcal{D}$ (i.e. reality), for which the learning rule yields expected error $1 / 2$
- More formally for any $A, m$ there exists $\mathcal{D}$ s.t. $\exists_{h^{*}} L\left(h^{*}\right)=0$ but

$$
\mathbb{E}_{S \sim D^{m}}[L(A(S))] \geq \frac{1}{2}-\frac{m}{2|X|}
$$

- Inductive Bias:
- Some realities (sources $\mathcal{D}$ ) are less likely; design $A$ to work well on more likely realities
e.g., by preferring certain $y \mid x$ (i.e. $h(x)$ ) over others
- Assumption or property of reality $\mathcal{D}$ under which $A$ ensures good generalization error
e.g., $\exists h \in \mathcal{H}$ with low $L(h)$
e.g., $\exists h$ with low "complexity" $c(h)$ and low $L(h)$

## Flat Inductive Bias

- "Flat" inductive bias: $\exists h^{*} \in \mathcal{H}$ with low $L\left(h^{*}\right)$
- (Almost) optimal learning rule:

$$
E R M_{\mathcal{H}}(S)=\hat{h}=\arg \min _{h \in \mathcal{H}} L_{S}(h)
$$

- Guarantee (in expectation over $S \sim \mathcal{D}^{m}$ ):

$$
L\left(E R M_{\mathcal{H}}(S)\right) \leq L\left(h^{*}\right)+\mathcal{R}_{m}(\mathcal{H}) \approx L\left(h^{*}\right)+\sqrt{\frac{\operatorname{capacity}(\mathcal{H})}{m}}
$$

$\rightarrow$ can learn with $O(\operatorname{capacity}(\mathcal{H}))$ samples

- E.g.
- For binary loss, capacity $(\mathcal{H})=V \operatorname{Cdim}(H)$
- For linear predictors over $d$ features, $\operatorname{capacity}(\mathcal{H})=d$
- Usually with $d$ parameters, capacity $(\mathcal{H}) \approx \tilde{O}(d)$
- For linear predictors with $\|w\|_{2} \leq B$, with logistic loss and normalized data: $\operatorname{capacity}(\mathcal{H})=B^{2}$

## Machine Learning

- We want model classes (hypothesis classes) that:
- Are expressive enough to capture reality well
- Have small enough capacity to allow generalization

## Complexity Measure as Inductive Bias

- Complexity measure: mapping $c: \mathcal{Y}^{\mathcal{X}} \rightarrow[0, \infty]$
- Associated inductive bias: $\exists h^{*}$ with small $c\left(h^{*}\right)$ and small $L\left(h^{*}\right)$
- Learning rule: $S R M_{\mathcal{H}}(S)=\arg \min L(h), c(h)$
e.g. $\quad \arg \min L(h)+\lambda c(h) \quad$ or $\arg \min L(h)$ s.t. $c(h) \leq B$ and choose $\lambda$ or $B$ using cross-validation
- Guarantee:

$$
\mathcal{H}_{B}=\{h \mid c(h) \leq B\}
$$

$$
L\left(S R M_{\mathcal{H}}(S)\right) \leq \approx L\left(h^{*}\right)+\sqrt{\frac{\operatorname{capacity}\left(\mathcal{H}_{c\left(h^{*}\right)}\right)}{m}}
$$

- E.g.:
- Degree of poly
- Sparsity
- \|w\|

## Feed-Forward Neural Networks (The Multilayer Perceptron)

$$
\begin{aligned}
& a[v]=\sum_{u \rightarrow v \in E} w[u \rightarrow v] o[u] \\
& o[v]=\sigma(a[v])
\end{aligned}
$$

## Architecture:

- Directed Acyclic Graph G(V,E). Units (neurons) indexed by vertices in V .
- "Input Units" $v_{1} \ldots v_{d} \in V$, with no incoming edges and $o\left[v_{i}\right]=x[i]$
- "Output Unit" $v_{\text {out }} \in V, h_{w}(x)=o\left[v_{\text {out }}\right]$
- "Activation Function" $\sigma: \mathbb{R} \rightarrow \mathbb{R}$. E.g. $\sigma_{R E L U}(z)=[z]_{+}$

## Parameters:

## Feed Forward Neural Networks

- Fix architecture (connection graph $G(V, E)$, transfer $\sigma$ )

$$
\mathcal{H}_{G(V, E), \sigma}=\left\{f_{w}(x)=\text { output of net with weights w }\right\}
$$

- Capacity / Generalization ability / Sample Complexity
- $\widetilde{O}(|E|)$ (number of edges, i.e. number of weights) (with threshold $\sigma$, or with RELU and finite precision; RELU with inf precision: $\widetilde{\Theta}(|E| \cdot$ depth))
- Expressive Power / Approximation
- Any continuous function with huge network
- Lots of interesting things naturally with small networks
- Any time $T$ computable function with network of size $\widetilde{\boldsymbol{O}}(T)$

## Free Lunches

- ML as an Engineering Paradigm: Use data and examples, instead of expert knowledge and tedious programming, to automatically create efficient systems that perform complex tasks
- We only care about $\{h \mid h$ is an efficient system $\}$
- Free Lunch: $T I M E_{T}=\{h \mid h$ comp. in time $T\}$ has capacity $O(T)$ and hence learnable with $O(T)$ samples, e.g. using ERM
- Even better: $\boldsymbol{P R O} \boldsymbol{G}_{T}=\{$ program of length $T\}$ has capacity $O(T)$
- Problem: ERM for above is not computable!
- Modified ERM for TIME (truncating exec. time) is NP-complete
- $\mathrm{P}=\mathrm{NP} \rightarrow$ Universal Learning is possible! (Free Lunch)
- Crypto is possible (one-way functions exist) $\rightarrow$ No poly-time learning algorithm for $T I M E_{T}$ (that is: no poly-time $A$ and uses poly $(T)$ samples s.t. if $\exists h^{*} \in T I M E_{T}$ with $L\left(h^{*}\right)=0$ then $\left.\mathbb{E}[L(A(S))] \leq 0.4\right)$

## No Free (Computational) Lunch

- Statistical No-Free Lunch: For any learning rule $A$, there exists a source $\mathcal{D}$ (i.e. reality), s.t. $\exists h^{*}$ with $L\left(h^{*}\right)=0$ but $\mathbb{E}[L(A(S))] \approx \frac{1}{2}$.
- Cheating Free Lunch: There exists $A$, s.t. for any reality $\mathcal{D}$ and any efficiently computable $\boldsymbol{h}^{*}, A$ learns a predictor almost as good as $h^{*}$ ( with \#samples=O(runtime of $h^{*}$ ), but a lot of time).
- Computational No-Free Lunch: For every computationally efficient learning algorithm $\boldsymbol{A}$, there is a reality $\mathcal{D}$ s.t. there is some comp. efficient (poly-time) $h^{*}$ with $L\left(h^{*}\right)=0$ but $\mathbb{E}[L(A(S))] \approx \frac{1}{2}$.
- Inductive Bias: Assumption or property of reality $\mathcal{D}$ under which a learning algorithm $A$ runs efficiently and ensures good generalization error.
- $\mathcal{H}$ or $c(h)$ are not sufficient inductive bias if ERM/SRM not efficiently implementable, or implementation doesn't always work (runs quickly and returns actual ERM/SRM).

## Feed Forward Neural Networks

- Fix architecture (connection graph $G(V, E)$, transfer $\sigma$ )

$$
\mathcal{H}_{G(V, E), \sigma}=\left\{f_{w}(x)=\text { output of net with weights } w\right\}
$$

- Capacity / Generalization ability / Sample Complexity
- $\widetilde{O}(|E|)$ (number of edges, i.e. number of weights) (with threshold $\sigma$, or with RELU and finite precision; RELU with inf precision: $\widetilde{\Theta}(|E| \cdot$ depth $))$
- Expressive Power / Approximation
- Any continuous function with huge network
- Lots of interesting things naturally with small networks
- Any time $T$ computable function with network of size $\widetilde{\boldsymbol{O}}(T)$
- Computation / Optimization
- Even if function exactly representable with single hidden layer with $\Theta(\log d)$ units, even with no noise, and even if we allow a much larger network when learning: no poly-time algorithm always works [Kearns Valiant 94; Klivans Sherstov 06; Daniely Linial Shalev-Shwartz '14]
- Magic property of reality that makes local search "work"

For valid generalization, the size of the weights is more important than the size of the network

- What is the relevant "complexity measure" (eg norm)?
- How is this minimized (or controlled) by the opt algorithm?
- How does it change if we change the opt algorithm?

Cross-Entropy

0/1 Training Error

0/1 Test Error

## SGD vs ADAM

Results on Penn Treebank using 3-layer LSTM
[Wilson Roelofs Stern S Recht, "The Marginal Value of Adaptive Gradient Methods in Machine Learning", NIPS'17]

## Different optimization algorithm

$\rightarrow$ Different bias in optimum reached $\rightarrow$ Different Inductive bias
$\rightarrow$ Different generalization properties

Need to understand optimization alg. not just as reaching some (global) optimum, but as reaching a specific optimum

Different optimization algorithm
$\rightarrow$ Different bias in optimum reached $\rightarrow$ Different Inductive bias
$\rightarrow$ Different generalization properties

Need to understand optimization alg. not just as reaching some (global) optimum, but as reaching a specific optimum

The Deep Recurrent Residual Boosting Machine Joe Flow, DeepFace Labs

Section 1: Introduction
We suggest a new amazing architecture and loss function that is great for learning. All you have to do to learn is fit the model on your training data

Section 2: Learning Contribution: our model
The model class $h_{w}$ is amazing. Our learning method is:

$$
\begin{equation*}
\arg \min _{w} \frac{1}{m} \sum_{i=1}^{m} \operatorname{loss}\left(h_{w}(x) ; y\right) \tag{*}
\end{equation*}
$$

Section 3: Optimization
This is how we solve the optimization problem (*): [...]
Section 4: Experiments
It works!

|  | 2 |  |  | 5 |  |  |  |  | 2 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 | 1 |  |  | 2 | 2 |  | 5 | 5 |  | 4 |
| 4 |  | 2 |  | 4 | 1 |  | 3 | 3 | 1 |  |
| 3 |  |  |  | 4 |  | 2 |  |  |  | 4 |
| 2 |  |  |  | 1 |  | +3 |  |  | 2 |  |
|  | 2 | 2 |  | V |  |  | 4 | 4 |  | 5 |
|  | 2 |  | 4 | 1 | 4 | 4 | 2 | 2 | 3 |  |
| 1 |  | 3 |  | 1 | 1 |  |  |  | 4 | 3 |
|  | 4 |  | 2 | 2 |  |  | 53 | 3 | 1 |  |

$$
\min _{X \in \mathbb{R}^{n \times n}}\|\operatorname{observed}(X)-y\|_{2}^{2} \equiv \min _{U, V \in \mathbb{R}^{n \times n}}\left\|\operatorname{observed}\left(U V^{\top}\right)-y\right\|_{2}^{2}
$$

- Underdetermined non-sensical problem, lots of useless global min
- Since $U, V$ full dim, no constraint on $X$, all the same non-sense global min

Different optimization algorithm
$\rightarrow$ Different bias in optimum reached $\rightarrow$ Different Inductive bias
$\rightarrow$ Different generalization properties

Need to understand optimization alg. not just as reaching some (global) optimum, but as reaching a specific optimum

## Deep Learning

- Expressive Power
- We are searching over the space of all functions...
... but with what bias? What (implicit) assumptions?
- How does this bias look? Is it reasonable/sensible?
- Capacity / Generalization ability / Sample Complexity
- What's the true complexity measure (inductive bias)?
- How does it control generalization?
- Computation / Optimization
- How and where does optimization bias us? Under what conditions?

Ultimate Question: What is the true Inductive Bias? What makes reality efficiently learnable by fitting a (huge) neural net with a specific algorithm?

## The "complexity measure" approach

Identify $c(h)$ s.t.

- Optimization algorithm biases towards low $c(h)$
- $\mathcal{H}_{c(\text { reality })}=\{h \mid c(h) \leq c($ reality $)\}$ has low capacity
- Reality is well explained by low $c(h)$
- Mathematical questions:
- What is the bias of optimization algorithms?
- What is the capacity (三sample complexity) of the sublevel sets $\mathcal{H}_{c}$ ?
- Question about reality (scientific Q?): does it have low $c(h)$ ?

## Simple Example: Least Squares

- Consider an under-constraint least-squares problem $(n<m)$ :

$$
\min _{w \in \mathbb{R}^{n}}\|A w-b\|^{2}
$$

```
A\in\mp@subsup{\mathbb{R}}{}{m\timesn}
```

- Claim: Gradient Descent (or SGD, or conjugate gradient descent, or BFGS) converges to the least norm solution

$$
\min _{A w=b}\|w\|_{2}
$$

$>$ Proof: iterates always spanned by rows of $A$ (more details soon)

# Implicit Bias in Least Squared $\min \|A w-b\|^{2}$ 

- Gradient Descent (+Momentum) on $w$
$\rightarrow \min _{A w=b}\|w\|_{2}$
- Gradient Descent on factorization $W=U V$
$\rightarrow \min _{A(W)=b}\|W\|_{*}$ with stepsize $\downarrow 0$ and init $\searrow 0$, only in special cases (commutative measurements; or incoherent problems)
- AdaGrad on $w$
$\rightarrow$ in some special cases $\min _{A w=b}\|w\|_{\infty}$, but not always, and it depends on stepsize, adaptation parameters, momentum
- Coordinate Descent (steepest descent w.r.t. $\|w\|_{1}$ )
$\rightarrow$ Related to, but not quite $\min _{A w=b}\|w\|_{1}$ (Lasso) (with stepsize $\downarrow 0$ and particular tie-breaking $\approx$ LARS)

## Implicit Bias in Logistic Regression

$$
\begin{gathered}
\arg \min _{w \in \mathbb{R}^{n}} \mathcal{L}(w)=\sum_{i=1}^{m} \ell\left(y_{i}\left\langle w, x_{i}\right\rangle\right) \\
\ell(z)=\log \left(1+e^{-z}\right)
\end{gathered}
$$

- Data $\left\{\left(x_{i}, y_{i}\right)\right\}_{i=1}^{m}$ linearly separable $\left(\exists_{w} \forall_{i} y_{i}\left\langle w, x_{i}\right\rangle>0\right)$
- Where does gradient descent converge?

$$
w(t)=w(t)-\eta \nabla \mathcal{L}(w(t))
$$

- $\inf \mathcal{L}(w)=0$, but minima unattainable
- GD diverges to infinity: $w(t) \rightarrow \infty, \mathcal{L}(w(t)) \rightarrow 0$
- In what direction? What does $\frac{w(t)}{\|w(t)\|}$ converge to?

## Implicit Bias in Logistic Regression

$$
\begin{gathered}
\arg \min _{w \in \mathbb{R}^{n}} \mathcal{L}(w)=\sum_{i=1}^{m} \ell\left(y_{i}\left\langle w, x_{i}\right\rangle\right) \\
\ell(z)=\log \left(1+e^{-z}\right)
\end{gathered}
$$

- Data $\left\{\left(x_{i}, y_{i}\right)\right\}_{i=1}^{m}$ linearly separable $\left(\exists_{w} \forall_{i} y_{i}\left\langle w, x_{i}\right\rangle>0\right)$
- Where does gradient descent converge?

$$
w(t)=w(t)-\eta \nabla \mathcal{L}(w(t))
$$

- $\inf \mathcal{L}(w)=0$, but minima unattainable
- GD diverges to infinity: $w(t) \rightarrow \infty, \mathcal{L}(w(t)) \rightarrow 0$
- In what direction? What does $\frac{w(t)}{\|w(t)\|}$ converge to?
- Theorem: $\frac{w(t)}{\|w(t)\|_{2}} \rightarrow \frac{\widehat{w}}{\|\widehat{w}\|_{2}} \quad \widehat{w}=\arg \min \|w\|_{2}$ s.t. $\forall_{i} y_{i}\left\langle w, x_{i}\right\rangle \geq 1$
[Soudry Hoffer S 2017] based on [Telgarsky 2013 "Margins, shrinkage, and boosting"]

## How Fast is the Margin Maximized?

Convergence to the max margin $\widehat{w}$ : *

$$
\left\|\frac{w(t)}{\|w(t)\|}-\frac{\widehat{w}}{\|\widehat{w}\|}\right\|=O\left(\frac{1}{\log t}\right)
$$

Convergence of the margin itself:

$$
\max _{\|w\| \leq 1} \min _{i} y_{i}\left\langle w, x_{i}\right\rangle-\min _{i} y_{i}\left\langle\frac{w(t)}{\|w(t)\|}, x_{i}\right\rangle=O\left(\frac{1}{\log t}\right)
$$

Contrast with convergence of the loss:

$$
\mathcal{L}(w(t))=O\left(\frac{1}{t}\right)
$$

$\rightarrow$ Even after we get extremely small loss, need to continue optimizing in order to maximize margin

| Epoch | 50 | 100 | 200 | 400 | 2000 | 4000 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $L_{2}$ norm | 13.6 | 16.5 | 19.6 | 20.3 | 25.9 | 27.54 |
| Train loss | 0.1 | 0.03 | 0.02 | 0.002 | $10^{-4}$ | $3 \cdot 10^{-5}$ |
| Train error | $4 \%$ | $1.2 \%$ | $0.6 \%$ | $0.07 \%$ | $0 \%$ | $0 \%$ |
| Validation loss | 0.52 | 0.55 | 0.77 | 0.77 | 1.01 | 1.18 |
| Validation error | $12.4 \%$ | $10.4 \%$ | $11.1 \%$ | $9.1 \%$ | $8.92 \%$ | $8.9 \%$ |

Training a conv net using SGD+momentum on CFAIR10

## Other Objectives and Opt Methods

- Single linear unit, logistic loss
$\rightarrow$ hard margin SVM solution (regardless of init, stepsize)
- Multi-class problems with softmax loss
$\rightarrow$ multiclass SVM solution (regardless of init, stepsize)
- Steepest Descent w.r.t. $\|w\|$
$\rightarrow \arg \min \|w\|$ s.t. $\forall_{i} y_{i}\left\langle w, x_{i}\right\rangle \geq 1$ (regardless of init, stepsize)
- Coordinate Descent
$\rightarrow \arg \min \|w\|_{1}$ s.t. $\forall_{i} y_{i}\left\langle w, x_{i}\right\rangle \geq 1$ (regardless of init, stepsize)
- Matrix factorization problems $\mathcal{L}(U, V)=\sum_{i} \ell\left(\left\langle A_{i}, U V^{\top}\right\rangle\right)$, including 1-bit matrix completion
$\rightarrow \arg \min \|W\|_{t r}$ s.t. $\left\langle A_{i}, W\right\rangle \geq 1$ (regardless of init)

## Different Asymptotics

- For least squares (or any other loss with attainable minimum):
- $w_{\infty}$ depends on initial point $w_{0}$ and stepsize $\eta$
- To get clean characterization, need to take $\eta \rightarrow 0$
- If 0 is a saddle point, need to take $w_{0} \rightarrow 0$
- For monotone decreasing loss (eg logistic)
- $w_{\infty}$ does NOT depend on initial $w_{0}$ and stepsize $\eta$
- Don't need $\eta \rightarrow 0$ and $w_{0} \rightarrow 0$
- What happens at the beginning doesn't effect $w_{\infty}$

## Single Overparametrized Linear Unit

Train single unit with SGD using logistic ("cross entropy") loss

## $\rightarrow$ Hard Margin SVM predictor

$$
w(\infty) \propto \arg \min \|w\|_{2} \text { s.t. } \forall_{i} y_{i}\left\langle w, x_{i}\right\rangle \geq 1
$$

## Even More Overparameterization: Deep Linear Networks

Network implements a linear mapping:

$$
f_{w}(x)=\left\langle\beta_{w}, x\right\rangle
$$

Training: same opt. problem as logistic regression:

$$
\min _{w} \mathcal{L}\left(f_{w}\right) \equiv \min _{\beta} \mathcal{L}(x \mapsto\langle\beta, x\rangle)
$$

Train $w$ with SGD
$\rightarrow$ Hard Margin SVM predictor
$\beta_{w(\infty)} \rightarrow \arg \min \|\beta\|_{2}$ s.t. $\forall_{i} y_{i}\left\langle\beta, x_{i}\right\rangle \geq 1$

L-1 hidden layers, $h_{l} \in \mathbb{R}_{D^{\prime}-1}^{n}$ each with (one channel) full-width cyclic "convolution" $w_{\ell} \in \mathbb{R}^{D}$ :

$$
h_{l}[d]=\sum_{k=0}^{D^{\prime}-1} w_{l}[k] h_{l-1}[d+k \bmod D] \quad h_{o u t}=\left\langle w_{L}, h_{L-1}\right\rangle
$$

With single conv layer ( $L=2$ ), training weights with SGD

## $\rightarrow \arg \min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{1}$ s.t. $\forall_{i} y_{i}\left\langle\beta, x_{i}\right\rangle \geq 1$

Discrete Fourier Transform
With multiple conv layers

$$
\rightarrow \text { critical point of } \min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{2 / L} \text { s.t. } \forall_{i} y_{i}\left\langle\beta, x_{i}\right\rangle \geq 1
$$

for $\ell(z)=\exp (-z)$, almost all linearly separable data sets and initializations $w(0)$ and any bounded stepsizes s.t. $\mathcal{L} \rightarrow 0$, and $\Delta w(t)$ converge in direction

## 

 $\min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{2 / L}$ s.t. $\forall_{i} y_{i}\left\langle\beta, x_{i}\right\rangle \geq 1$

$\min \|\beta\|_{2 / L}$ s.t. $\forall_{i} y_{i}\left\langle\beta, x_{i}\right\rangle \geq 1$
L=5 Network solution

- Binary matrix completion (also: reconstruction from linear measurements)
- $\boldsymbol{X}=U V$ is over-narametrization of all matrices $X \in \mathbb{R}^{n \times m}$
- GD on $U, V$
$\rightarrow$ implicitly minimize $\|X\|_{*}$
- Linear Convolutional Network:
- Complex over- .. .. . .... .. . $\beta$
- GD on weights (or explicitly minimize \|weights\| $\|_{2}$ )
$\rightarrow$ implicitly $\min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{p}$ for $p=\frac{2}{\text { depth }}$ (sparsity in freq domain)

- Binary matrix completion (also: reconstruction from linear measurements)
- $\boldsymbol{X}=U V$ is over-parametrization of all matrices $X \in \mathbb{R}^{n \times m}$
- GD on $U, V$
$\rightarrow$ implicitly minimize $\|X\|_{*}$
[Gunasekar Lee Soudry S 2018a]
- Linear Convolutional Network:
- Complex over-parametrization of all linear predictors $\beta$
- GD on weights
$\boldsymbol{\rightarrow}$ implicitly $\min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{p}$ for $p=\frac{2}{\text { depth }}$ (sparsity in freq domain)
[Gunasekar Lee Soudry S 2018b]
- Infinite Width ReLU Net:
- Parametrization of essentially all functions $h: \mathbb{R}^{d} \rightarrow \mathbb{R}$
- GD on weights
$\rightarrow$ implicitly minimize $\max \left(\int\left|\boldsymbol{h}^{\prime \prime}\right| \boldsymbol{d} \boldsymbol{x},\left|h^{\prime}(-\infty)+h^{\prime}(+\infty)\right|\right) \quad(\mathrm{d}=1)$

$$
\begin{equation*}
\int\left|\partial_{b}^{d+1} \operatorname{Radon}(h)\right| \tag{d>1}
\end{equation*}
$$

(need to define more carefully to handle non-smoothness; correction term for linear part) [Savarese Evron Soudry S 2019][Ongie Willett Soudry S 2020][Chizat Bach 2020]

## All Functions

Parameter Space

Optimization Geometry and hence Inductive Bias effected by:

- Geometry of local search in parameter space
- Choice of parameterization

## Artificial Neural Networks Deep Learning Computer Netwc

## How is an Embedding layer useful to a learning task if it is just a dense layer with no activation function? If this 'linear hidden layer' is taken out, the network should still be able to learn the same function.

Interesting

Request

- Binary matrix completion (also: reconstruction from linear measurements)
- $\boldsymbol{X}=U V$ is over-parametrization of all matrices $X \in \mathbb{R}^{n \times m}$
- GD on $U, V$ (or explicitly minimize $\|U\|_{F}^{2}+\|V\|_{F}^{2}$ )
$\rightarrow$ implicitly minimize $\|X\|_{*}$
[Gunasekar Lee Soudry S 2018a]
- Linear Convolutional Network:
- Complex over-parametrization of all linear predictors $\beta$
- GD on weights (or explicitly minimize \|weights $\|_{2}^{2}$ )
$\rightarrow$ implicitly $\min \|\boldsymbol{D F T}(\boldsymbol{\beta})\|_{p}$ for $p=\frac{2}{\text { depth }}$ (sparsity in freq domain)
[Gunasekar Lee Soudry S 2018b]

$$

(need to define more carefully to handle non-smoothness; correction term for linear part)
[Savarese Evron Soudry S 2019][Ongie Willett Soudry S 2020][Chizat Bach 2020]

- Does Implicit Bias of Gradient Descent just boil down to regularizing $\|$ weights $\|_{2}$ ?
- Answer: sort of, at least asymptotically with logistic/exp loss, for $D$-homogenous models (details soon)
...but we'll later see that not quite

## Model: $\boldsymbol{F}(w)=h_{w} \quad$ Model Class: $\mathcal{H}=\operatorname{range}(\boldsymbol{F})$

$f(w, x)=h_{w}(x)=$ prediction on $x$ with params ("weights") $w$
Linear models: $f(w, x)=\left\langle\beta_{w}, x\right\rangle \quad F(w)=\beta_{w}$

$$
\text { Loss: } L_{S}(w)=\frac{1}{m} \sum_{i} \ell\left(f\left(w, x_{i}\right), y_{i}\right)
$$

$D$-homogenous: $F(c w)=c^{D} F(w)$, i.e. $f(c w, x)=c^{D} f(w, x)$

- 1-homogenous: standard linear $F(w)=w, f(w, x)=\langle w, x\rangle$
- 2-homogenous:
- Matrix factorization $F(U, V)=U V$
- 2-Layer ReLU: $f(W, x)=\sum_{j} w_{2, j}\left[\left\langle w_{1, j}, x\right\rangle\right]_{+}$
- D-homogenous:
- D layer linear network
- D layer linear conv net
- D layer ReLU net

$$
\ell_{\text {logistic }}(h(w), y)=\log \left(1+e^{-y h(w)}\right) \approx e^{-y h(w)}=\ell_{\exp }(h(w), y)
$$

Consider gradient descent w.r.t. logistic loss $L_{s}(w)=\sum_{i} \ell\left(f\left(w, x_{i}\right) ; y_{i}\right)$ (or other exp-tail loss) on a D-homogenous model $f(w, x)$

- 1-homogenous: standard linear $F(w)=w, f(w, x)=\langle w, x\rangle$
- 2-homogenous:
- Matrix factorization $F(U, V)=U V$
- 2-Layer ReLU: $f(W, x)=\sum_{j} w_{2, j}\left[\left\langle w_{1, j}, x\right\rangle\right]_{+}$
- D-homogenous:
- D layer linear network
- D layer linear conv net
- D layer ReLU net

$$
\ell_{\text {logistic }}(h(w), y)=\log \left(1+e^{-y h(w)}\right) \approx e^{-y h(w)}=\ell_{\exp }(h(w), y)
$$

Consider gradient descent w.r.t. logistic loss $L_{s}(w)=\sum_{i} \ell\left(f\left(w, x_{i}\right) ; y_{i}\right)$ (or other exp-tail loss) on a D-homogenous model $f(w, x)$ :

Theorem [Nacson Gunasekar Lee S Soudry 2019][Lyu Li 2019]:
If $L_{S}(w) \rightarrow 0$, and small enough stepsize (ensuring convergence in direction):
$\boldsymbol{w}_{\infty} \propto$ first order stationary point of

$$
\arg \min \|w\|_{2} \text { s.t. } \forall_{i} y_{i} f\left(w, x_{i}\right) \geq 1
$$

Suggests implicit bias defined by $\boldsymbol{R}_{F}(\boldsymbol{h})=\arg \min _{F(\boldsymbol{w})=h}\|w\|_{2}$ and

$$
\boldsymbol{h}_{\infty}=\boldsymbol{F}\left(\boldsymbol{w}_{\infty}\right) \propto \text { first order stationary point of }
$$

$$
\begin{equation*}
\arg \min R_{F}(h) \text { s.t. } y_{i} f\left(x_{i}\right) \geq 1 \tag{*}
\end{equation*}
$$

But need to be careful: f.o.s.p of (*) does not imply f.o.s.p of (**)

- But what about squared loss?

$$
\begin{gathered}
\ell(h(w) ; y)=(h(w)-y)^{2} \\
\mathrm{GD} \text { on } L_{s}(w)=\sum_{i} \ell\left(f\left(w, x_{i}\right) ; y_{i}\right)
\end{gathered}
$$

- What optimization choices and hyperparameters effect the implicit bias and how? E.g.
- Stepsize
- Initialization
- Initialize $w(0)=\alpha w_{0}$ (we will want to take $\alpha \rightarrow 0$ )
- Stepsize $\rightarrow 0$, so i.e. gradient flow:

$$
\dot{w}_{\alpha}=-\nabla L_{S}(w) \quad \text { and } \quad w_{\alpha}(0)=\alpha w_{0}
$$

We are interested in $w_{\alpha}(\infty)=\lim _{t \rightarrow \infty} w_{\alpha}(t)$

Consider a "linear diagonal net" (ie linear regression with squared parametrization):

$$
f(w, x)=\sum_{j}\left(w_{+}[j]^{2}-w_{-}[j]^{2}\right) x[j]=\langle\beta(w), x\rangle \quad \text { with } \beta(w)=w_{+}^{2}-w_{-}^{2}
$$

And initialization $w_{\alpha}(0)=\alpha 1$ (so that $\beta\left(w_{\alpha}(0)\right)=0$ ).
What's the implicit bias of grad flow w.r.t square loss $L_{s}(w)=\sum_{i}\left(f\left(w, x_{i}\right)-y_{i}\right)^{2}$ ?

$$
\beta_{\alpha}(\infty)=\lim _{t \rightarrow \infty} \beta\left(w_{\alpha}(t)\right)
$$

$$
f(w, x)=w^{\top} \operatorname{diag}(w)\left[\begin{array}{l}
+x \\
-x
\end{array}\right]
$$

$$
\beta(t)=w_{+}(t)^{2}-w_{-}(t)^{2} \quad L=\|X \beta-y\|_{2}^{2}
$$

$$
\dot{w}_{+}(t)=-\nabla L(t)=-2 X^{\top} r(t) \circ \frac{d \beta}{d w_{+}}
$$

$$
r(t)=X \beta(t)-y
$$

$$
\begin{array}{cc}
\beta(t)=w_{+}(t)^{2}-w_{-}(t)^{2} & L=\|X \beta-y\|_{2}^{2} \\
\dot{w}_{+}(t)=-\nabla L(t)=-2 X^{\top} r(t) \circ 2 w_{+}(t) & w_{+}(t)=w_{+}(0) \circ \exp \left(-2 X^{\top} \int_{0}^{t} r(\tau) d \tau\right) \\
\dot{w}_{-}(t)=-\nabla L(t)=+2 X^{\top} r(t) \circ 2 w_{-}(t) & w_{-}(t)=w_{-}(0) \circ \exp \left(+2 X^{\top} \int_{0}^{t} r(\tau) d \tau\right)
\end{array}
$$

$$
\beta(t)=\alpha^{2}\left(e^{-4 X^{\top} \int_{0}^{t} r(\tau) d \tau}-e^{4 X^{\top} \int_{0}^{t} r(\tau) d \tau}\right) \quad r(t)=X \beta(t)-y
$$

$$
\begin{gathered}
s=4 \int_{0}^{\infty} r(\tau) d \tau \in \mathbb{R}^{m} \\
\beta(\infty)=\alpha^{2}\left(e^{-X^{\top} S}-e^{X^{\top} S}\right)=2 \alpha^{2} \sinh X^{\top} S \\
X \beta(\infty)=y
\end{gathered}
$$

$\min Q(\beta)$ s.t. $X \beta=y$

$$
\nabla Q\left(\beta^{*}\right)=X^{\top} v
$$

$$
\beta(\infty)=\alpha^{2}\left(e^{-X^{T} S}-e^{X^{\top} S}\right)=2 \alpha^{2} \sinh X^{\top} S
$$

$$
X \beta^{*}=y
$$

$$
X \beta(\infty)=y
$$

$$
\begin{aligned}
& \nabla Q(\beta)=\sinh ^{-1} \frac{\beta}{2 \alpha^{2}} \\
& Q(\beta)=\sum_{i} \int \sinh ^{-1} \frac{\beta[i]}{2 \alpha^{2}}=\alpha^{2} \sum_{i}\left(\frac{\beta[i]}{\alpha^{2}} \sinh ^{-1} \frac{\beta[i]}{2 \alpha^{2}}-\sqrt{4+\left(\frac{\beta[i]}{\alpha^{2}}\right)^{2}}\right)
\end{aligned}
$$

$\min Q(\beta)$ s.t. $X \beta=y$

$$
\begin{gathered}
\nabla Q\left(\beta^{*}\right)=X^{\top} v \\
X \beta^{*}=y
\end{gathered}
$$

$$
\begin{gathered}
\sinh ^{-1} \frac{\beta(\infty)}{2 \alpha^{2}}=X^{\top} S \\
X \beta(\infty)=y
\end{gathered}
$$

## Linear Diagonal Nets

$$
f(w, x)=\sum_{j}\left(w_{+}[j]^{2}-w_{-}[j]^{2}\right) x[j]=\langle\beta(w), x\rangle \quad \text { with } \beta(w)=w_{+}^{2}-w_{-}^{2}
$$

With initialization $w_{\alpha}(0)=\alpha 1$ (so that $\beta\left(w_{\alpha}(0)\right)=0$ ).

Implicit bias of grad flow w.r.t square loss: $\beta_{\alpha}(\infty)=\boldsymbol{\operatorname { a r g }} \min _{\boldsymbol{X} \boldsymbol{\beta}=\boldsymbol{y}} \boldsymbol{Q}_{\alpha}(\boldsymbol{\beta})$
where $Q_{\alpha}(\beta)=\sum_{j} q\left(\frac{\beta[j]}{\alpha^{2}}\right)$ and $q(b)=2-\sqrt{4+b^{2}}+b \sinh ^{-1}\left(\frac{b}{2}\right)$

Induced dynamics:

$$
\dot{\beta}_{\alpha}=-\sqrt{\beta_{\alpha}^{2}+4 \alpha^{4}} \odot \nabla L_{s}\left(\beta_{\alpha}\right)
$$

If $\alpha \rightarrow \infty$ (Kernel Regime): $\beta_{\alpha}(\infty) \xrightarrow{\alpha \rightarrow \infty} \hat{\beta}_{L 2}=\arg \min _{X \beta=y}\|\beta\|_{2}$
If $\alpha \rightarrow 0$ ("Rich" Regime): $\beta_{\alpha}(\infty) \xrightarrow{\alpha \rightarrow 0} \hat{\beta}_{L 1}=\arg \min _{X \beta=y}\|\beta\|_{1}$

$$
\beta_{\alpha}(\infty)=\arg \min _{X \beta=y} Q_{\alpha}(\beta)
$$

where $Q_{\alpha}(\beta)=\sum_{j} q\left(\frac{\beta[j]}{\alpha^{2}}\right)$ and $q(b)=2-\sqrt{4+b^{2}}+b \sinh ^{-1}\left(\frac{b}{2}\right)$

Theorem 2. For any $0<\epsilon<d$,

$$
\alpha \leq \min \left\{\left(2(1+\epsilon)\left\|\boldsymbol{\beta}_{L 1}^{*}\right\|_{1}\right)^{-\frac{2+\epsilon}{2 \epsilon}}, \exp \left(-\frac{d}{\epsilon\left\|\boldsymbol{\beta}_{L 1}^{*}\right\|_{1}}\right)\right\} \Longrightarrow\left\|\hat{\boldsymbol{\beta}}_{\alpha}\right\|_{1} \leq(1+\epsilon)\left\|\boldsymbol{\beta}_{L 1}^{*}\right\|_{1}
$$

Theorem 3. For any $\epsilon>0$

$$
\alpha \geq \sqrt{2(1+\epsilon)\left(1+\frac{2}{\epsilon}\right)\left\|\boldsymbol{\beta}_{L 2}^{*}\right\|_{2}} \Longrightarrow\left\|\hat{\boldsymbol{\beta}}_{\alpha}\right\|_{2}^{2} \leq(1+\epsilon)\left\|\boldsymbol{\beta}_{L 2}^{*}\right\|_{2}^{2}
$$

## Sparse Learning

$$
\begin{gathered}
y_{i}=\left\langle\beta^{*}, x_{i}\right\rangle+N(0,0.01) \\
d=1000, \quad\left\|\beta^{*}\right\|_{0}=5, \quad m=100
\end{gathered}
$$

## Sparse Learning

$$
\begin{aligned}
& y_{i}=\left\langle\beta^{*}, x_{i}\right\rangle+N(0,0.01) \\
& d=1000, \quad\left\|\beta^{*}\right\|_{0}=k
\end{aligned}
$$

How small does $\alpha$ need to be to get $L\left(\beta_{\alpha}(\infty)\right)<0.025$

## Is implicit bias of GD just $\ell_{2}$ in param space + mapping to func space?

Is initializing to $w(0)=\alpha 1$ the same as regularizing distance to $\alpha \mathbf{1}$ ?

$$
\beta_{\alpha}^{R}=F\left(\arg \min _{L_{s}(w)=0}\|w-\alpha 1\|_{2}^{2}\right)=\arg \min _{X \beta=y} R_{\alpha}(\beta)
$$

Where $R_{\alpha}(\beta)=\min _{F(w)=\beta}\|w-\alpha \mathbf{1}\|_{2}^{2}$

## Is implicit bias of GD just $\ell_{2}$ in param space + mapping to func space?

Is initializing to $w(0)=\alpha 1$ the same as regularizing distance to $\alpha \mathbf{1}$ ?

$$
\beta_{\alpha}^{R}=F\left(\arg \min _{L_{S}(w)=0}\|w-\alpha 1\|_{2}^{2}\right)=\arg \min _{X \beta=y} R_{\alpha}(\beta)
$$

Where $R_{\alpha}(\beta)=\min _{F(w)=\beta}\|w-\alpha \mathbf{1}\|_{2}^{2}$
$R_{\alpha}(\beta)=\sum_{j} r\left(\frac{\beta[j]}{\alpha^{2}}\right)$ where $r(b)$ is solution of quartic equation:

$$
r^{4}-6 r^{3}+\left(12-2 b^{2}\right) r^{2}-\left(8+10 b^{2}\right) r+b^{2}+b^{4}=0
$$

## Deep Diagonal Linear Net

$$
\beta(t)=w_{+}(t)^{D}-w_{-}(t)^{D}
$$

## Deep Diagonal Linear Net

$$
\begin{aligned}
& \beta(t)=w_{+}(t)^{D}-w_{-}(t)^{D} \\
& \beta(t)=\alpha^{D}\left(\left(1+\alpha^{D-2} D(D-2) X^{\top} \int_{0}^{t} r(\tau) d \tau\right)^{\frac{-1}{D-2}}-\left(1-\alpha^{D-2} D(D-2) X^{\top} \int_{0}^{t} r(\tau) d \tau\right)^{\frac{-1}{D-2}}\right)
\end{aligned}
$$

KKT for $\min Q(\beta)$ st. $X \beta=y:$

$$
X \beta^{*}=y
$$

$$
\begin{array}{r}
s=\alpha^{D-2} D(D-2) \int_{0}^{\infty} r(\tau) d \tau \in \mathbb{R}^{m} \\
\beta(\infty)=\alpha^{D} h_{D}\left(X^{\top} S\right) \\
X \beta(\infty)=y \\
\left.h_{D}(z)=\alpha^{D}\left(\left(1+\alpha^{D-2} D(D-2) z\right)\right)^{\frac{-1}{D-2}}-\left(1-\alpha^{D-2} D(D-2) z\right)^{\frac{-1}{D-2}}\right)
\end{array}
$$

$$
\begin{gathered}
q_{D}=\int h_{D}^{-1} \\
Q_{D}(\beta)=\sum_{i} q_{D}\left(\frac{\beta[i]}{\alpha^{D}}\right)
\end{gathered}
$$

## Deep Diagonal Linear Net

$$
\beta(t)=w_{+}(t)^{D}-w_{-}(t)^{D} \quad \beta(\infty)=\arg \min Q_{D}\left(\beta / \alpha^{D}\right) \text { s.t. } X \beta=y
$$

- Depth 2
-Depth 3
- Depth 5
- Depth 15

$$
h_{D}(z)=\alpha^{D}\left(\left(1+\alpha^{D-2} D(D-2) z\right)^{\frac{-1}{D-2}}-\left(1-\alpha^{D-2} D(D-2) z\right)^{\frac{-1}{D-2}}\right)
$$

$$
\begin{aligned}
q_{D} & =\int h_{D}^{-1} \\
Q_{D, \alpha}(\beta) & =\sum_{i} q_{D}\left(\frac{\beta[i]}{\alpha^{D}}\right)
\end{aligned}
$$

## Deep Diagonal Linear Net

$$
\beta(t)=w_{+}(t)^{D}-w_{-}(t)^{D} \quad \beta(\infty)=\arg \min Q_{D}\left(\beta / \alpha^{D}\right) \text { s.t. } X \beta=y
$$

- Depth 2
- Depth 3
- Depth 5
- Depth 15

For all depth $D \geq 2, \beta(\infty) \xrightarrow{\alpha \rightarrow 0} \arg \min _{X \beta=y}\|\beta\|_{1}$

- Contrast with explicit reg: For $R_{\alpha}(\beta)=\min _{\substack{\beta=w_{+}^{D}-w_{\mathrm{D}} \underline{D} \\ \text { also observed by [Arora Cohen Hu Luo 2019] }}}\|w-\alpha \mathbf{1}\|_{2}^{2}, \quad R_{\alpha}(\beta) \xrightarrow{\alpha \rightarrow 0}\|\beta\|_{2 / D}$
- Also with logistic loss, $\beta(\infty) \rightarrow \propto$ SOSP of $\|\beta\|_{2 / D}$
[Gunasekar Lee Soudry Srebro 2018]
[Lyu Li 2019]
- With sq loss, always $\|\cdot\|_{1}$, but we get there if quicker depth is higher

## Logistic Loss vs Squared Loss

## Depth two:

- Square loss: $\beta(\infty) \propto \arg \min _{X \beta=y} Q_{\alpha}(\beta)$
- Logistic loss: $\forall_{\alpha} \beta(\infty) \propto \arg \min _{X \beta=y}\|\beta\|_{1}$

Deeper Diagonal Nets:

- Squared loss, $\beta(\infty) \xrightarrow{\alpha \rightarrow 0} \propto \arg \min _{X \beta=y}\|\beta\|_{1}$
- Logistic loss, $\beta(\infty) \propto$ SOSP of $\|\beta\|_{2 / D}$

[Moroshko Gunasekar Woodworth Lee S Soudry 2020 "Implicit Bias in Deep Linear Classification: Initialization Scale vs Training Accuracy"]

## Implicit bias of optimization (and hence inductive bias) effected by:

- Parametrization (architecture)
- Optimization "geometry" (GD vs AdaGrad vs coordinate methods)
- Type (asymptotics) of loss function
- Initialization
- Optimization accuracy
- Early stopping
- Not so early stopping
- Stepsize, momentum, other opt. parameters
- Stochasticity (SGD vs GD, mini-batch size, label noise)
[Cheng Chatterji Bartlett Jordan 2018][HaoChen Wei Lee Ma 2020]
- ???

## The "complexity measure" approach

Identify $c(h)$ s.t.

- Optimization algorithm biases towards low $c(h)$
- $\mathcal{H}_{c(\text { reality })}=\{h \mid c(h) \leq c($ reality $)\}$ has low capacity
- Reality is well explained by low $c(h)$

Can optimization bias can be described as $\arg \min \boldsymbol{c}(\boldsymbol{h})$ s.t. $\boldsymbol{L}_{\boldsymbol{S}}(\boldsymbol{h})=\mathbf{0}$ ??

- Not always [Dauber Feder Koren Livni 2020]
- Approximately? Enough to explain generalization??

Ultimate Question: What is the true Inductive Bias? What makes reality efficiently learnable by fitting a (huge) neural net with a specific algorithm?

## Deep Learning

- Expressive Power
- We are searching over the space of all functions...
... but with what inductive bias?
- How does this bias look in function space?
- Is it reasonable/sensible?
- Capacity / Generalization ability / Sample Complexity
- What's the true complexity measure (inductive bias)?
- How does it control generalization?
- Computation / Optimization
- How and where does optimization bias us? Under what conditions?
- Magic property of reality under which deep learning "works"
